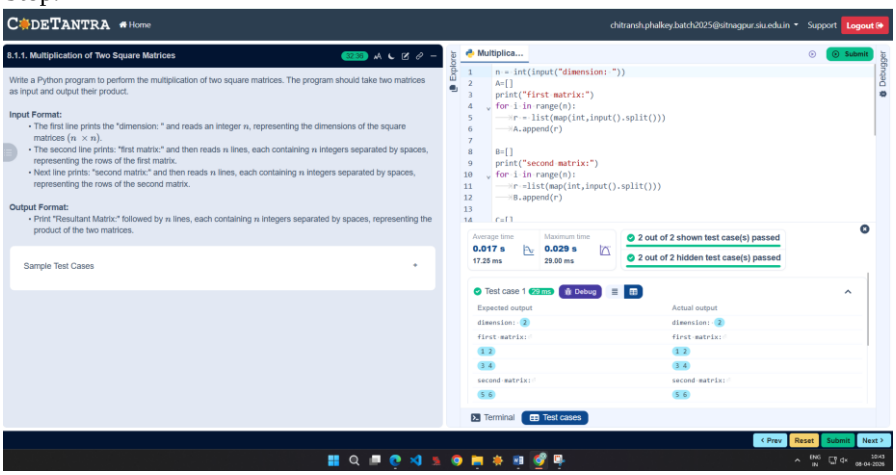
Experiment

08:Problem Statement:-

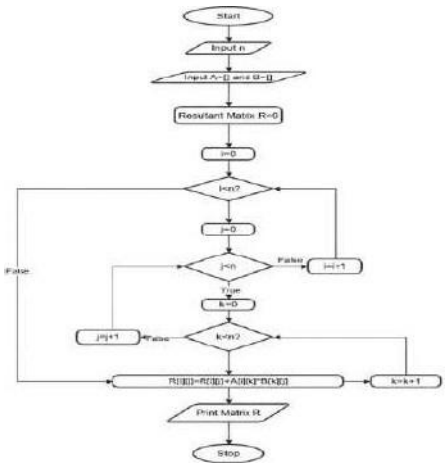
Write a Python program to perfonn the multiplication of two square matrices.
The program should take two matrices as input and output their product.

Algorithm:-

1. Start.
2. Input the order n of the square matrices.
3. Input elements of Matrix A and Matrix B.
4. Create a result matrix R of size n x 11 and initialize all elements to 0.
5. Initialize loop variable i from 0 to .
6. Inside that, initialize loop variable j from 0 to n—l.
7. Inside that, initialize loop variable k from 0 to n—l.
8. Perform multiplication and addition: If inside loops —+R[i][j] = R[i][j] +
9. Repeat until all loops finish.
10. Plint the result matrix R.
11. Stop.



Flowchart:-



Execution:-

Problem Statement:-

Write a Python program to print all prime numbers within a given range (inclusive of both start and end values).

Algorithm:-

I Start

2. Input the values start and stop.
3. Set found = False.
4. Repeat for each number num from start to stop.
5. Check if num > 1.
6. Repeat for i from 2 to N/num.
7. Check condition:

   If num 0 0 i 0 break (number is not prime).
8. If no divisor is found, then:

   Print num

   Set found = Tme.
9. After the loop, check found.

10. If found = False —+ Print "No primes".
11. Stop
